

CurveLab

A launch-design workspace for Meteora DBC

Crypto World's Fair · Meteora DBC track

The launch configuration problem

A curve sets the terms of early participation

Launchpad builders must understand how liquidity distribution changes price movement and graduation capital requirements.

CurveLab makes these choices observable before a builder signs a launch transaction.

Graduation reserves depend on the curve

Same supply and market-cap targets; different liquidity weights

1B TOKEN
30 → 300 SOL market
cap
1% fixed DBC fee

SOL quote reserves
Calculated by the official SDK

Balanced = equal weights · Patient = more early liquidity · Momentum = more late liquidity

Identical trades expose different outcomes

Buy 1 SOL → Buy 2 SOL → Sell 1M TOKEN → Buy 5 SOL

Balanced

212.1M

TOKEN held

11.05% graduation progress

Patient launch

236.6M

TOKEN held

15.30% graduation progress

Momentum

161.0M

TOKEN held

8.22% graduation progress

Official SDK swap quotes · reproducible JSON exports · simulation only

The working design workspace

Adjust launch parameters

Compare three SDK configurations
Inspect the price-discovery curves
Export parameters and experiment results

React frontend + local Node API

Meteora integration and current validation

Official DBC SDK

buildCurveWithLiquidityWeights → quote and scenario math → configuration and pool-creation transaction

Devnet launch flow

Phantom signature, preflight, confirmation and pool lookup are implemented. Configurations target DAMM v2; migration uses the official manual migrator.

Release status and next milestones

Verified local MVP

SDK curve generation and simulations work. Tests, build and browser checks pass.

Chain validation remains pending

A Devnet faucet error blocked funded pool creation. No confirmed launch or DAMM migration is claimed. Upstream dependency findings remain documented.

Next: funded Devnet lifecycle → launchpad-builder feedback → broader configurations
